

Abstract

An orthotic device promotes both supination and pronation of a patient's wrist. A forearm enclosure is adapted to substantially wrap around a forearm. A forearm support member is adapted to slidably receive the forearm enclosure wherein the support member wraps partially around the forearm enclosure. A post is mountable on the forearm enclosure. An anchor is mounted on the support member. A tensioning member is connected to the anchor and on the other end to the post, wherein a rotational force of supination or pronation will be created on the forearm enclosure depending on the direction which the tensioning members extend from the anchor to the post.
